

Full regression — report

BytePe production · 6 Aug 2026 · 149 tests · branch `restore-login-session`

No product defects found, and the suite is now fully green. The final run passed 121 of 121 with retries off. Every earlier failure traced to the environment — rate limiting, a local DNS dropout, or an expired login session. Three genuine defects were found in the test suite itself, and all three are fixed.

149	121	0	3	31
TESTS	PASSED, 0 FAILED	PRODUCT BUGS	SUITE BUGS FIXED	SKIPPED

Runs

Run	Mode	Passed	Failed	Skipped	Mins	Verdict
Run 1	3 workers, retries off	118	3	31	2.8	All 3 failures were HTTP 429 rate limiting
Run 2	3 workers, retries off	116	5	31	2.9	Timeouts on search and navigation under load
Run 3	3 workers, retries on	110	9	31	3.7	Local DNS stopped resolving mid-run
FINAL	2 workers, retries off	121	0	31	3.6	Whole suite green with nothing hidden by retries

"Retries off" is the strict view — it hides nothing. The suite normally runs with one retry, which absorbs transient load failures.

Every failure, and its cause

ID	Cause	Tests affected	Product broken?	Status
F-01	Rate limiting (HTTP 429)	3 tests, 122 URLs	No	Fixed in this session
F-02	Local DNS failure	9 tests	No	Environmental
F-03	Session expired mid-run	up to 12 tests	No	Fixed in this session
F-04	Contention under 3 workers	2-5 tests per run, never the same ones	No	Fixed in this session

Fixed in this session F-01 — Rate limiting (HTTP 429)

What happened	site-health reported 122 product pages as dead; search /search returned 429 instead of 404
Evidence	"Aisle Trunk Check-in Luggage ... -> 429", "Expected: 404 Received: 429"
Why	site-health sweeps all 186 catalogue pages, 6 at a time, using a plain request.get with no retry — while the rest of the suite is also hitting production. The origin throttles, and a 429 was counted as a dead page.
Fix	FIXED — site-health now uses getWithRetry (retries 429/502/503/504 with backoff) and its concurrency dropped from 6 to 4. The search route check retries past a 429 before asserting 404.

Environmental F-02 — Local DNS failure

What happened	Every navigation failed to resolve the hostname partway through Run 3
Evidence	net::ERR_NAME_NOT_RESOLVED https://www.bytepe.com/ getaddrinfo ENOTFOUND www.bytepe.com
Why	The test machine lost DNS resolution mid-run. Nothing to do with the site or the specs — connectivity checked immediately afterwards returned HTTP 200 in 0.43s.
Fix	No code change. Re-run when the network is stable. Worth knowing so a DNS blip is not misread as a site outage.

Fixed in this session

F-03 — Session expired mid-run

What happened	Login-gated specs fail immediately with "Saved login session is unusable"
Evidence	<code>Saved login session is unusable – access_token expired 2026-08-06 06:29:17Z</code>
Why	The access token lasts exactly 15 minutes, measured from the JWT claims (issued 11:36:20Z, expires 11:51:20Z). The suite takes 3-4 minutes, so auth done more than ~10 minutes earlier leaves the gated specs failing before their first assertion. The guard working as designed, not a defect.
Fix	FIXED — the refresh_token lasts 7 days and the app renews the access_token itself via POST /api/auth/refresh-tokens. That call fires on an authenticated route, which auth-setup was not loading, so it demanded an OTP that was never needed. It now visits /my-profile first. Verified: with the access_token deleted, npm run auth recovered in 6.1s with no OTP.

Fixed in this session

F-04 — Contention under 3 workers

What happened	Clicks and navigations time out at 30s on controls that are plainly present
Evidence	<code>TimeoutError: locator.click: Timeout 30000ms exceeded page.waitForURL: Timeout 30000ms</code>
Why	Three workers plus site-health's own sweep is more load than production answers comfortably. The specs pass in a smaller set — 103 passed with retries off when run without the gated ones.
Fix	FIXED — workers dropped from 3 to 2. Measured with retries off: 3 workers gave 118/3 and 116/5; 2 workers gave 121 passed, 0 failed. Costs about 45 seconds. Retries had been absorbing the difference, which meant a real regression would have looked like the usual noise.

Coverage by area

Area	Tests	Result
Smoke (homepage, core pages)	9	Pass
Catalogue health (186 products)	4	Pass — 186/186 live
Search + product search	9	Pass
Product pricing / data-driven	8	Pass
Cardless EMI + EMI plan config	38	Pass
EMI tenure ladder	8	Pass
Pincode (valid / invalid / pricing)	6	Pass
Category browsing	9	Pass
Cart + checkout flow	3	Pass
Subscription end-to-end	2	Pass — mints a real order
EMI store flow	1	Pass
Coupons (valid / invalid)	2	Pass
Account / addresses / orders	8	Pass
Product video (API + rendering)	31	Skipped — no live video exists

What to do next

#	Action	Why
---	--------	-----

1	Ask backend about the token TTL — no longer needed	Measured from the JWT: 15 min access, 7 day refresh. Ordinary values, no regression. An earlier note in this report claimed the TTL had changed from ~12 hours; that was an inference, not a measurement, and was wrong.
2	Decide workers — done, now 2	Closed. 121 passed, 0 failed with retries off, versus 2-5 failures a run at 3 workers.
3	Get a valid fixed OTP	Lower priority now. The refresh flow already gives unattended auth for 7 days at a time; a fixed OTP would only matter when the refresh_token itself expires.
4	Re-run when the network is stable	Run 3's nine failures were a local DNS dropout, not the site.
